Data-driven Digital Healthcare:

Longitudinal Data Analytics for Parkinson's Disease

George Roussos
g.roussos@bbk.ac.uk

LONDON'S EVENING UNIVERSITY

Birkbeck
UNIVERSITY OF LONDON

Overview

- cloudUPDRS certified Class I Medical Device for clinical use
- Rate PD motor symptoms as precisely as an experienced clinician
- Extends and adapts Part III of the standard UPDRS protocol
- Unsupervised use at home
  - Employs accelerometer for tremor and gait measurements
  - Employs touch-screen for tapping measurements
  - No clinical or technical supervision during testing: bespoke user journey
- Data analytics

Birkbeck
UNIVERSITY OF LONDON

Challenges

1. Ensure unsupervised test is carried out correctly
2. Reduce testing time
3. Capture symptom variability
4. Identify high quality signal segments

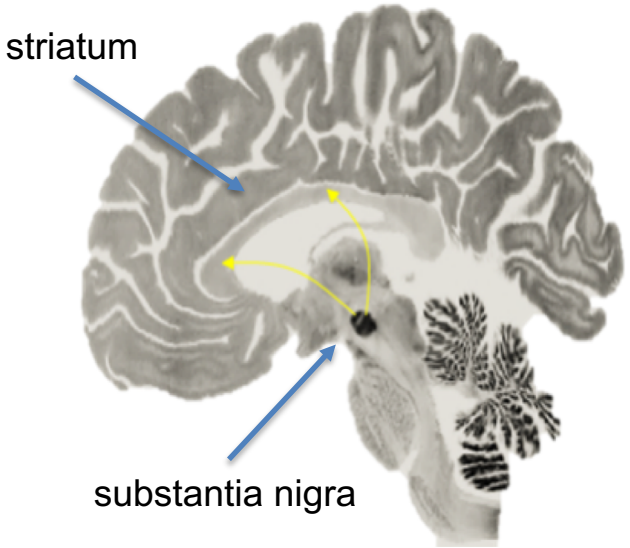
Birkbeck
UNIVERSITY OF LONDON

People with Parkinson's

Parkinson's Disease (PD)

- No cure
- Managed mainly by replacing dopamine

- Motor symptoms
  - tremor, rigidity, slowness of movement (bradykinesia), freezing of gait, stiffness, shaking, falls
- Non-motor symptoms
  - bladder, memory, sleep, addictive behaviour, fatigue, pain, hallucinations



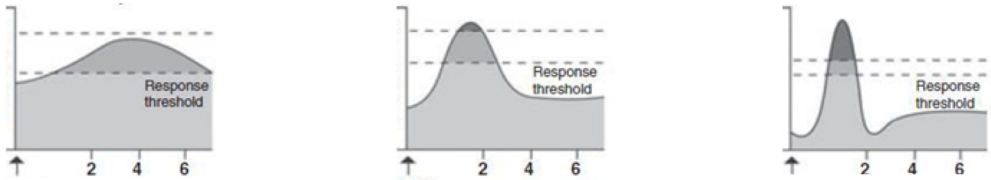
Symptoms of Parkinson's Disease

Disease Progression

Prodromal	Early	Moderate	Complex
Sleep disorder Loss of smell Constipation Depression	Slowness Stiffness Shaking Urgency	Anxiety Low blood pressure Dyskinesias Impulsivity Freezing	Brittle ON/OFF's Cognitive impairment Pain Hallucinations

Impairment

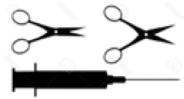
Time (years)



Levodopa response

?	Levodopa MAOI Agonists	COMT Agonists	Deep brain stimulation Apomorphine Duodopa

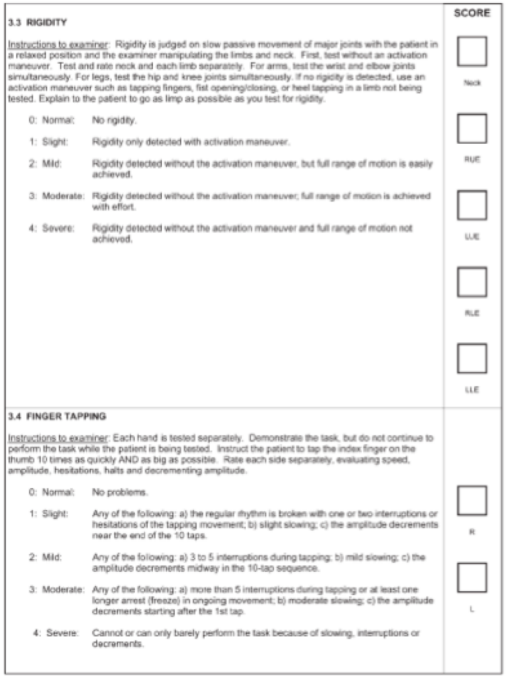
Treatments



UNIFIED PARKINSON'S DISEASE RATING SCALE

- Standard clinical protocol for assessing PD
- Part III clinical assessment of motor symptoms
- Known issues:
  - time intensive
  - inter-rater variability
  - not sensitive
- Used formally
  - Drug trials
  - Consideration of advanced therapies
- Used informally as part of clinical assessment (once or twice per year) of disease progression

- Can we replace with an app?



3.3 RIGIDITY — SCORE

Instructions to examiner: Rigidity is judged on slow passive movement of major joints with the patient in a relaxed position and the examiner manipulating the limbs and neck. First, test without an activation maneuver. Test and rate neck and each limb separately. For arms, test the wrist and elbow joints simultaneously. For legs, test the hip and knee joints simultaneously. If no rigidity is detected, use an activation maneuver such as tapping fingers, fist opening/closing, or heel tapping in a limb not being tested. Explain to the patient to go as limp as possible as you test for rigidity.

- 0: Normal: No rigidity.
- 1: Slight: Rigidity only detected with activation maneuver.
- 2: Mild: Rigidity detected without the activation maneuver, but full range of motion is easily achieved.
- 3: Moderate: Rigidity detected without the activation maneuver; full range of motion is achieved with effort.
- 4: Severe: Rigidity detected without the activation maneuver and full range of motion not achieved.

Neck ☐ RUE ☐ LUE ☐ RLE ☐ LLE ☐

3.4 FINGER TAPPING

Instructions to examiner: Each hand is tested separately. Demonstrate the task, but do not continue to perform the task while the patient is being tested. Instruct the patient to tap the index finger on the thumb 10 times as quickly AND as big as possible. Rate each side separately, evaluating speed, amplitude, hesitations, halts and decrementing amplitude.

- 0: Normal: No problems.
- 1: Slight: Any of the following: a) the regular rhythm is broken with one or two interruptions or hesitations of the tapping movement; b) slight slowing; c) the amplitude decrements near the end of the 10 taps.
- 2: Mild: Any of the following: a) 3 to 5 interruptions during tapping; b) mild slowing; c) the amplitude decrements midway in the 10-tap sequence.
- 3: Moderate: Any of the following: a) more than 5 interruptions during tapping or at least one longer arrest (freeze) in ongoing movement; b) moderate slowing; c) the amplitude decrements starting after the 1st tap.
- 4: Severe: Cannot or can only barely perform the task because of slowing, interruptions or decrements.

Expressed use intentions

- Quantitative and qualitative methods
  - survey and audience panels
- Majority of PD patients would use app (86%)
  - Most would prefer the test to last less than 5 minutes per assessment (64%)
  - Some would accept up to 10 minutes (27%)
- Main motivation: Need to understand their condition
- No expressed privacy concerns

cloudUPDRS app

- Design objectives:
  - Sensitive to patient mobility constraints
  - Sensitive to patient cognitive impairments

- Approach:
  - Constrain user context for reliable interpretation of data
  - Encourage frequent use

CUSSP Clinical Study

Visit 1 Day -60 to 0 (Screening): Discuss study, PIS given

↓

Visit 2 Day 0 (Eligibility): Written consent, MOCA, PDQ39, Beck's administered, baseline demographics recorded, App installed

↓

Visit 3 Day 1-150 (Hospital UPDRS): Official Enrolment, assessments as follows with order *randomised:*
a) Clinical video UPDRS (OFF/ON)*
b) Smartphone UPDRS (OFF/ON)*

↓

Home monitoring period (order of A, B and C pseudorandomised) (3 consecutive weeks, starting on Day 1- 150)		
Week 1	6 days of home monitoring+ (method A)	Baseline smartphone OFF/ ON test on 7th day* Visit 4+
Week 2	6 days of home monitoring + (method B)	Baseline smartphone OFF/ ON test on 7th day* Visit 5+
Week 3	6 days of home monitoring + (method C)	Visit 6+

Birkbeck
UNIVERSITY OF LONDON

Unsupervised patient use

- Achieve firm user adherence to the prescribed movements
  - Accept test record only when movement executed correctly
  - Reject test when movement does not match expectations
- Use deep learning to learn movement features
- Apply offline or online (i.e. at the server on in the app)
- Use Tensorflow to learn and apply model

Tremor signal

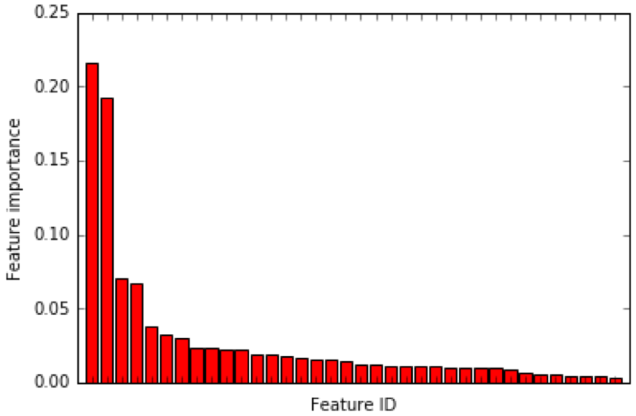
Birkbeck
UNIVERSITY OF LONDON

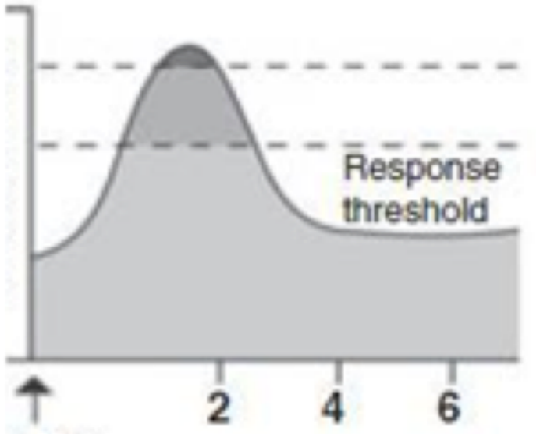
Quick Test

- UPDRS exhaustive search of all possible symptoms
- Each patient presents only a few
- Symptoms typically change slowly e.g. 6 months
- ~6 features are predictive of overall score
- Use ML to identify the specific tests that offer the highest inferential power
  - Observer five full tests
  - Apply standard ensemble of randomized decision tree method to rank tests according to predictive strength
  - Select top 3 tests for individualised quick test



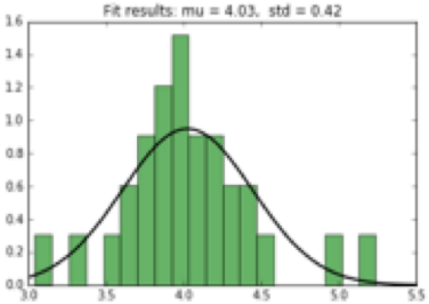
Limitations of current practice

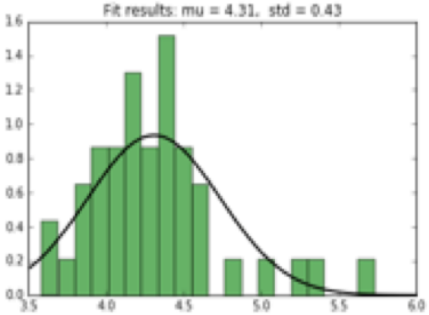
- Minimum Detectable Change (MDC95) ~12 (range 0-108)
- Typical annual disease progression 3-4 points
- Idealised response model
- Rapid uphill, slow downhill
- Affected by numerous parameters e.g. mood, social interaction, diet, exercise etc
- One sample has extremely limited value



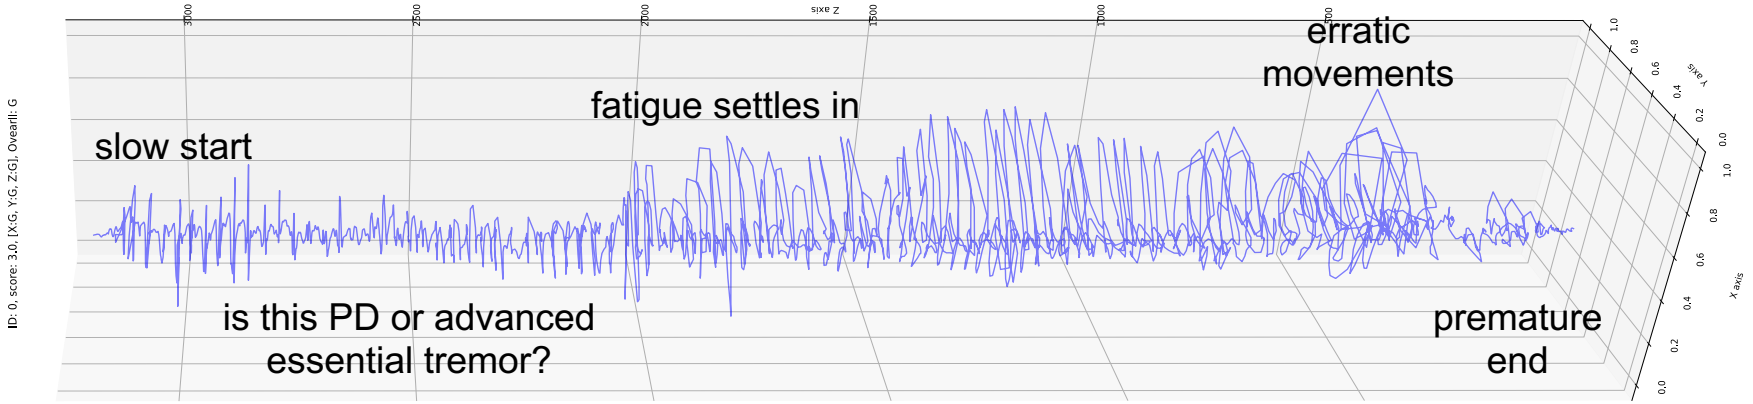
Capturing temporal variability

- Tremor signal is not stationary but is often treated as such (not unreasonable due to measurement limitations)
- Consider tremor to be a random process
- Look at temporal aggregates
- Preliminary results suggest far superior MDC95

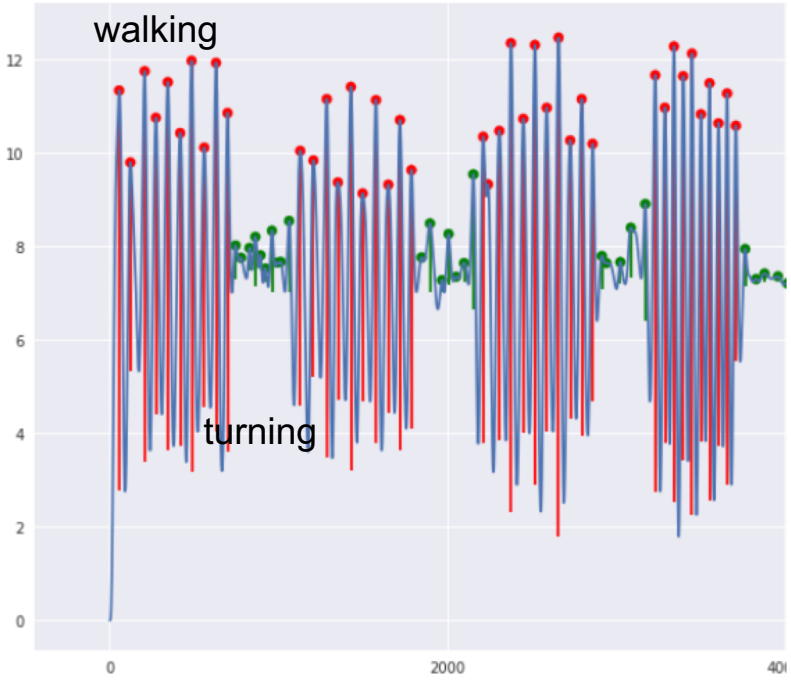




What is actually measured?



Gait test/activity recognition with HMM



How precisely can we detect the onset of turning movements?
Healthy subjects turn differently than PwP.

Birkbeck
UNIVERSITY OF LONDON

Closing remarks

- Move from clinician to automated diagnosis and treatment offers great opportunities to realise patient benefits
- Challenges often relate to having to change methods
- This can be intensified by the greater availability of data
- Stationary to dynamic processes, non-linearity
- Validated evidence is time consuming/expensive to collect
